| Parallel Databases |              |             |                             |

- increased transaction requirements
- increased volumes of data (particularly in data-warehousing
- Many queries lend themselves easily to parallel execution
- Can reduce time required to retrieve relations from disk by partitioning relations onto a set of disks
- Horizontal partitioning usually used. Subsets of a relation are sent to different disks

| i aritioning approaches |              |             |                             |

# **Round Robin**

- Assume *n* disks.
- With Round Robin: Relation is scanned in some order. The *i*<sup>th</sup> relation is sent to disk *D<sub>i</sub>modn*
- Guarantees an even distribution.

### **Hash Partitioning**

- choose attributes to act as partitioning attributes.
- define a hash function with range  $0 \dots n-1$
- Each tuple is placed according to the result of the hash function

# **Range Partitioning**

- partitioning attribute is chosen
- Partitioning vector is defined < v<sub>0</sub>, v<sub>1</sub>, ... v<sub>n-2</sub> >
- tuples are placed according to value of partitioning attribute. If t[partitioning attribute] < v<sub>0</sub>, place tuple t on disk D<sub>0</sub>

# **Query Types**

## Common types of queries

- Scanning entire relation (batch processing)
- Point-Queries (return all tuples that match some value)
- Range-Queries (return all tuples with some value in some range)

| Introduction | Partitioning | Parallelism | Intra-Operation Parallelism |
|--------------|--------------|-------------|-----------------------------|
|              | 0000         |             |                             |
|              |              |             |                             |

# Comparison of Partitioning techniques

- Round Robin
  - useful for batch processing
  - not very suitable for point or range querying as all disks have to be accessed.

| Introduction | Partitioning | Parallelism | Intra-Operation Parallelism |
|--------------|--------------|-------------|-----------------------------|
|              | 0000         |             |                             |
|              |              |             |                             |

# **Comparison of Partitioning techniques**

- Round Robin
  - useful for batch processing
  - not very suitable for point or range querying as all disks have to be accessed.
- Hash partitioning
  - very useful if point query based on partitioning attribute.
  - usually useful for batch querying is a fair hash function is used
  - poor for range querying

| Introduction | Partitioning | Parallelism | Intra-Operation Parallelism |
|--------------|--------------|-------------|-----------------------------|
|              | 0000         |             |                             |
|              |              |             |                             |

# Comparison of Partitioning techniques

- Round Robin
  - useful for batch processing
  - not very suitable for point or range querying as all disks have to be accessed.
- Hash partitioning
  - very useful if point query based on partitioning attribute.
  - usually useful for batch querying is a fair hash function is used
  - poor for range querying
- Range Partitioning
  - Useful for point and range querying
  - Can lead to inefficiency in range querying if many tuples satisfy condition

| Introduction | Partitioning |
|--------------|--------------|
|              |              |

### **Inter-query Parallelism**

- different transactions run in parallel on different processors
- Transaction throughput is increased
- The times for individual queries remains the same
- easiest form of parallelism to implement

| Introduction | Partitioning | Parallelism | Intra-Operation Parallelism |
|--------------|--------------|-------------|-----------------------------|
| o            | 0000         | ○●          |                             |
|              |              |             |                             |

### Intra-query parallelism

- Can run a single query in parallel on multiple processors (and disks)
- Can speed up running time of query
- Can achieve parallel execution by parallelising individual components (intra-operation parallelism)
- Can also achieve parallel execution by evaluating portions of the query in parallel (inter-operation parallelism)
- Can also combine both

| Introduction                | Partitioning | Parallelism | Intra-Operation Parallelism |
|-----------------------------|--------------|-------------|-----------------------------|
| o                           | 0000         | oo          |                             |
| Intra-Operation Parallelism |              |             |                             |

### **Parallel Sorting**

#### Range-Partitioning Sort

- Distribute the relation using a range-partitioning strategy on the sort attribute
- Each subset is sorted in parallel. The final merge is not expensive due to the range partitioning strategy chosen

| Introduction                | Partitioning | Parallelism | Intra-Operation Parallelism |
|-----------------------------|--------------|-------------|-----------------------------|
| o                           | 0000         | oo          |                             |
| Intra-Operation Parallelism |              |             |                             |

#### **Parallel External Sort-Merge**

- Relation is partitioned.
- Each processor *P<sub>i</sub>* sorts the tuples at *D<sub>i</sub>*
- The sorted runs are then merged in parallel.
- Sorted runs are range-partitioned across a set of processors.
- Each processor performs a merge on the incoming streams
- These sorted runs are then concatenated.

|                             |                      |                   |                             |

#### **Partitioned Join**

- Partition relations across the n processors
- Compute  $r_0 \bowtie s_0$  at at processor  $P_0$ ,  $r_1 \bowtie s_1$  at processor  $P_1$  etc.
- can partition relations using hash or range partitioning
- suitable for equi-joins; not suitable for other types.

- Compute  $r_0 \bowtie s_0$  at at processor  $P_0$ ,  $r_1 \bowtie s_1$  at processor  $P_1$  etc.
- can partition relations using hash or range partitioning
- suitable for equi-joins; not suitable for other types.

#### **Fragment and Replicate**

- Wish to calculate  $r \bowtie_{x>y} s$
- partition *r* across the processors
- s is replicated at all processors
- $r_i \bowtie_{x>y} s$  is calculated at all processors
